

Robot kinematics

Václav Hlaváč

Czech Technical University in Prague

Czech Institute of Informatics, Robotics and Cybernetics

166 36 Prague 6, Jugoslávských partyzánů 3, Czech Republic

<http://people.ciirc.cvut.cz/hlavac>, vaclav.hlavac@cvut.cz

also Center for Machine Perception, <http://cmp.felk.cvut.cz>

Outline of the talk:

1. Kinematics, what is?
2. Open, closed kinematic mechanisms.
3. Sequence of joint transformations (matrix multiplications).
4. Direct vs. inverse kinematic task.

Initial comments

- ◆ We will refer here to a robot as a proxy for a mechanical device, its position, stiffness or dynamics is of interest.
- ◆ The terms and laws studied here can be applied to an industrial manipulator, any other robot, and any other mechanism with moving components.

Mechanics and its parts

Kinematics analyzes the **geometry of a motion** analytically, e.g. of a robot:

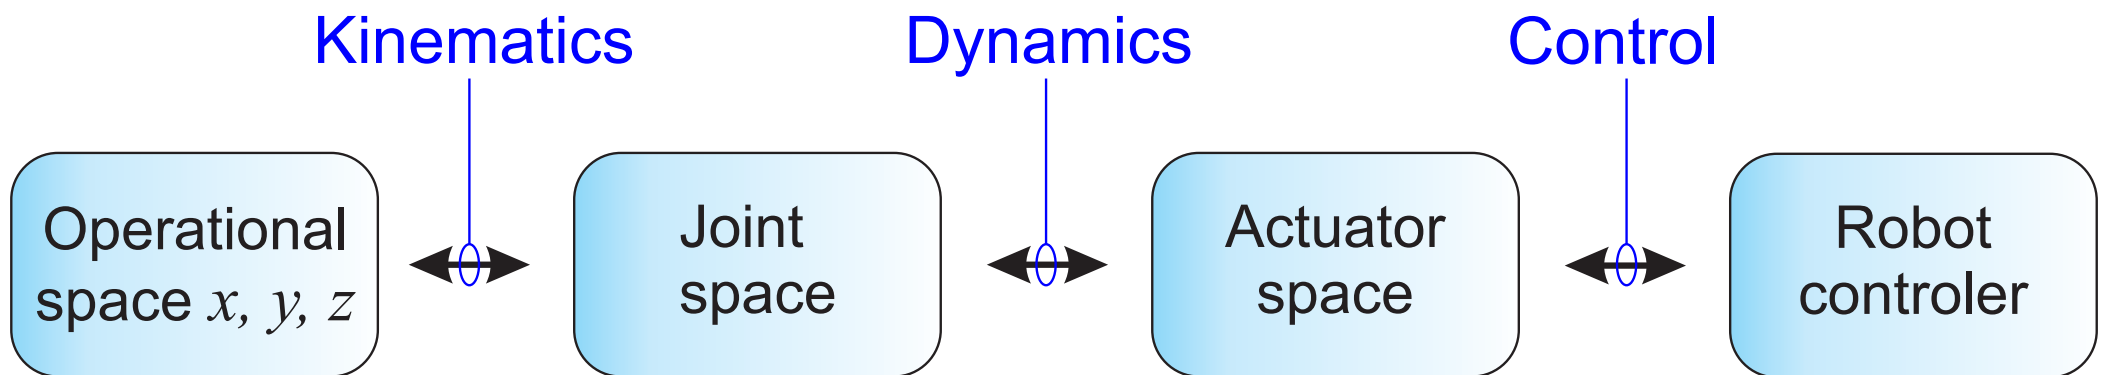

- ◆ With respect to a fixed reference co-ordinate system.
- ◆ Without regard to the forces or moments that cause the motion.
- ◆ Essential concepts are position and orientation.

Statics deals with forces and moments applied on the mechanism, which is not moving. The essential concepts used are **stiffness** $[Nm^{-1}]$ and **stress** $[Nm^2]$.

Dynamics analyzes **forces** $[N]$ and **moments** $[Nm]$, which result from motion and acceleration $[ms^{-2}]$ of the mechanism and the load.

Need of kinematics in robotics

- ◆ Knowing the kinematical description of a robot is a prerequisite of its control and programming.
- ◆ Kinematics provides knowledge of both robot spatial arrangement and a means of reference to the environment.
- ◆ Kinematics is only the first step towards robot control !

Kinematics – Terminology

- ◆ **Link** is the rigid part of the robot body (e.g. forearm).
- ◆ **Joint** is a part of the robot body which allows controlled or free relative motion of two links (connection element).
- ◆ **End effector** is the link of the manipulator which is used to hold the tools (gripper, spray gun, welding gun ...).
- ◆ **Base** is the link of the manipulator, which is usually connected to the ground and is directly connected to the world coordinate system.
- ◆ **Kinematic pair** is a pair of links, which relative motion is bounded by the joint connecting them (e.g. base and shoulder connected by J1 axis).

Open chain manipulator kinematics

- ◆ Mechanics of a manipulator can be represented as a kinematic chain of rigid bodies (links) connected by revolute or prismatic joints.
- ◆ Kinematics can be represented by an acyclic graph (tree). Example: human hand.
- ◆ One end of the chain is constrained to a base, while an end effector is mounted to the free end of the chain.
- ◆ The resulting motion is obtained by **composition of the elementary motions** of each link with respect to the previous one.

Open chain manipulators, examples

Closed kinematic chain

- ◆ Much more difficult. Can be represented by a (general, cyclic) graph.
- ◆ Even analysis has to take into account statics, constraints from other links, etc.
- ◆ Synthesis of closed kinematic mechanisms is very difficult.
- ◆ Main advantage = **higher stiffness**.

Closed kinematic chain examples

Hybrid chain

Parallel chain

Kinematics vs. differential kinematics

in a special case of an open kinematic chain mechanism, e.g. a robotic manipulator

- ◆ **Kinematics** describes the analytical relationship between the joint positions and the end-effector position and orientation.
- ◆ **Differential kinematics** describes the analytical relationship between the joint motion and the end-effector motion in terms of velocities.

Degrees of Freedom, a free rigid object

- ◆ Q: How many parameters (Degrees of Freedom, DoF) are needed to specify a flying rigid body?
A: **Six**, three coordinates of the position x, y, z , and three rotation angles.
- ◆ Example: Kinematics of the airplane allows it to move anywhere in the 3D space.

Degrees of freedom, example, question

- ◆ Q: How many degrees of freedom (DoF) this manipulator has?

- ◆ A:

Degrees of freedom, example, answer

- ◆ Q: How many degrees of freedom (DoF) has this manipulator?

- ◆ A: Six again. $2 \text{ base} + 1 \text{ shoulder} + 1 \text{ elbow} + 2 \text{ wrist} = 6$.

Kinematic joints, a quiz

Q: Joints examples: How many degrees of freedom they have?

Cardan joint

3D gimbal

spherical

A:

Kinematic joints, answers to the quiz

Q: How many degrees of freedom?

Cardan joint

3D gimbal

spherical

A: 2 DOFs

3 DOFs
singularities

3 DOFs
no singularities

Kinematic joints

Planar
3 DOF

Spherical
3 DOF

Cylindrical
2 DOF

Revolute
1 DOF

Prismatic
1 DOF

Helical
1 DOF

Structure of manipulators – Cartesian – PPP

Cartesian

Gantry

Structure of manipulators – Cylindrical – RPP

Structure of manipulators – Spherical – RRP

Structure of manipulators – Angular – RRR

Called also: anthropomorphic

Structure of manipulators – SCARA – RRRP

Structure of manipulators – Stewart platform

- ◆ Parallel kinematics.
- ◆ 6 DoFs.
- ◆ 6 prismatic actuators, commonly hydraulic jacks.
- ◆ Called also 6-axes platform or hexapod.
- ◆ Designed by V. E. Gough in 1954 for tyre testing.
- ◆ Published by D. Stewart in 1965.

Stewart platform, applications

Large jacks

FANUC

Flight simulator

Hexamod

Real hexamod

Joint and operational spaces, motivation

Example: a 3 DOF planar manipulator

Concepts:

joint space, joint coordinates;

operational space, operational coordinates

Joint space.

Operational space.

Direct vs. inverse kinematics

In an **open chain kinematic** manipulator robotics, there are two kinematic tasks:

1. **Direct (also forward) kinematics**

Given: Joint relations (rotations, translations) for the robot arm.

Task: What is the orientation and position of the end effector?

2. **Inverse kinematics**

Given: The desired end effector position and orientation.

Task: What are the joint rotations and orientations to achieve this?

In a more general case of **close kinematic chain** mechanisms, a more general statement is needed:

1. **Direct kinematics**

Given: the geometric structure of the manipulator and the values of a number of joint positions equal to the number of degrees of freedom of the mechanism.

Task: Find a relative position and orientation of any two designed joints.

2. **Inverse kinematics**

Given: a relative position and orientation of any two designed joints.

Task: Find values of all joints position and orientations.

Coordinate frames

Two basic types of joints

Revolute

Prismatic

Manipulator description

- ◆ Links: n moving links, 1 fixed link (base).
- ◆ Joints: revolute (1 DOF), prismatic (1 DOF).

Configuration parameters

- ◆ Configuration parameters are given by a set of positions describing the full configuration of the system.

- ◆ Generalized coordinates – a set of independent configuration parameters.
- ◆ Degrees of freedom – number of generalized coordinates.

Generalized coordinates (1)

6 parameters
(3 positions, 3 orientations)

n unconstraint moving links $\Rightarrow 6n$ parameters.

Generalized coordinates (2)

- ◆ n moving links $\Rightarrow 6n$ parameters.
- ◆ n 1 DOF joints $\Rightarrow 5n$ constraints.
- ◆ The system has $6n - 5n = n$ DOFs.

End-effector configuration parameters

- ◆ O – Origin of the world coordinates at the manipulator base.
- ◆ O_{n+1} – Operational point, the representative point of the end-effector.
- ◆ (x_1, x_2, \dots, x_m) – A set of parameters, which specifies the end-effector position and orientation with respect to coordinate system O .

Operational (joints) coordinates

- ◆ (x_1, x_2, \dots, k) – A set of k , $k \leq m$ independent configuration parameters.
- ◆ m_0 – number of end-effector degrees of freedom.

Manipulator redundancy

- ◆ n is the degree of freedom of a manipulator (robot).
- ◆ m_0 is the number of the end effector DoFs, 3 in the example.
- ◆ A manipulator (robot) is redundant if $n > m_0$.
- ◆ Degrees of redundancy = $n - m_0$.

Example: a planar manipulator in 2D.

Two frames kinematic relationship

- ◆ There is a kinematic relationship between two frames, basically a translation and a rotation.
- ◆ This relationship is represented by a 4×4 homogeneous transformation matrix.

Homogeneous transformation

$$\begin{array}{c}
 \text{3x3 rotation matrix} \\
 \\
 \\
 \\
 \text{1x3 perspective}
 \end{array}
 \left[\begin{array}{ccc|c}
 r_1 & r_2 & r_3 & \Delta x \\
 r_4 & r_5 & r_6 & \Delta y \\
 r_7 & r_8 & r_9 & \Delta z \\
 \hline
 0 & 0 & 0 & 1
 \end{array} \right]
 \begin{array}{c}
 \text{3x1 translation} \\
 \\
 \\
 \text{global scale}
 \end{array}$$

Rotation matrix R is orthogonal $\Leftrightarrow R^T R = I \Rightarrow$ 3 independent entries, e.g., Euler angles.

Kinematic open chain

Direct vs. inverse kinematics, a reminder

In an **open chain kinematic** manipulator robotics, there are two kinematic tasks:

1. **Direct (also forward) kinematics**

Given: Joint relations (rotations, translations) for the robot arm.

Task: What is the orientation and position of the end effector?

2. **Inverse kinematics**

Given: The desired end effector position and orientation.

Task: What are the joint rotations and orientations to achieve this?

Direct kinematics

- ◆ One joint: $\mathbf{x}_i = A\mathbf{x}_{i-1}$.
- ◆ Chain of joints: $\mathbf{x}_{n-1} = A_{n-1} A_{n-2} \dots A_1 A_0 \mathbf{x}_0$.
- ◆ Easy to compute (matrix multiplication).
- ◆ Unique solution.

Inverse kinematics

- ◆ For an open chain kinematic mechanism (a robot), the inverse kinematic problem is difficult to solve.
- ◆ The robot controller must solve a set of non-linear simultaneous algebraic equations.
- ◆ Source of problems:
 - Non-linear equations (\sin , \cos in rotation matrices).
 - The existence of multiple solutions.
 - The possible non-existence of a solution.
 - Singularities.

Kinematic decoupling \Rightarrow inverse kinematics becomes simpler

- ◆ Divide and conquer strategy. Decouple the problem into independent subproblems.
- ◆ General inverse kinematic (IK) task is difficult. However, for 6-DOF manipulators with the last 3 joint axes intersecting at one point, IK simplifies to two simpler tasks: (a) inverse position kinematics, (b) inverse orientation kinematics.
- ◆ The spherical wrist. Positioning of the wrist + positioning within the wrist.

- ◆ Design conventions, e.g. Denavit-Hartenberg systematic frame assignment.

Methods solving the inverse kinematics task

1. **Closed-form solutions.** Relevant for industrial manipulators.
 - ◆ Algebraic methods.
 - ◆ Geometric methods.
2. **Numerical methods.**
 - ◆ *Symbolic elimination methods*: involve analytical manipulations to eliminate variables from a system of nonlinear equations to reduce it to a smaller set of equations.
 - ◆ *Continuation methods*: involve tracking a solution path from a start system with known solutions to a target system.
 - ◆ *Iterative methods*: are in general based on Newton-Raphson method for finding roots using 1st order approximation of the original algebraic equation. They converge in a single solution (from several possible) based on the initial guess.
